The Science of Food: Raising Agents Knowledge Organiser

Mechanical Raising Agents	Action	Uses
Sieving	Traps air in between the flour particles.	cakes, pastry, batter
Whisking	Whisking eggs will trap air and create a foam.	meringues, cakes, mousse, sponges
Rubbing in	Rubbing fat into the flour adds air.	pastry, cakes
Creaming	Mixing fat and sugar together traps air – fat becomes pale and mixture is creamy.	cakes, sponges
Lamination	Air is trapped in each layer when it is rolled and folded.	flaky pastry, rough puff pastry

Chemical Raising Agents	Action	Uses
Bicarbonate of soda	With moisture and heat, the bicarbonate	chocolate cake, gingerbread
	creates bubbles of carbon dioxide which	
	raises the food. This can have a soapy	
	flavour.	
Baking powder	A mixture of baking powder and cream	Provides an 'all in one' method of baking
	of tartar works in the same way as	when 'creaming' isn't done to add air.
	bicarbonate of soda but with a reduced	
	'soapy' flavour.	
Self-raising flour	Plain flour with baking powder added	cake recipes
	removes the need to add a raising agent	
	individually.	
Creaming	Mixing fat and sugar together traps air –	cakes, sponges
	fat becomes pale and mixture is creamy.	
Lamination	Air is trapped in each layer when it is	flaky pastry, rough puff pastry
	rolled and folded.	

Physical Raising Agents	Action	Uses
Steam	Cooking a mixture	Yorkshire
	with a lot of liquid	pudding,
	in a very hot oven.	choux
	Water turns to	pastry
	steam, which causes	
	food to become solid	
	and rise.	

The Science of Food: Raising Agents Knowledge Organiser

Heat Control

Oven	Food can spoil if the correct temperature is not
	used.
	 If cake browns too quickly, reduce the heat by one
	gas mark or 10°C.

Hob

· Water boils at 100°C.

 Oil and fat can catch fire if they become too hot (between 180 and 250°C).

Grill

· The element should be red before grilling food.

 Food must be monitored to check it doesn't burn but cooks through

Biological Raising Agent	Action	Uses
Yeast	Yeast is a living organism that can be bought fresh or dried.	doughs, breads
	With moisture, food, oxygen and time, yeast will produce carbon dioxide bubbles. These cause bread dough to grow and rise.	
	After kneading, dough will be left to prove to allow yeast to become activated.	
	As dough rises, the gluten becomes stretchy, resulting in the dough being soft and springy.	
	Some bakers knock back the dough and allow it to have a second rise for a finer texture	

Troubleshooting

Problem	Cause	Products This Can Affect
The mixture is stodgy, dry and stiff.	too much flour	cakes, breads, biscuits
The mixture lacks volume, is too runny or too soft.	too little flour	baked products and sauces
The product has a rubbery, greasy possibly crunchy texture.	too much fat	all food products
The product is dry and lack flavour.	too little fat	baked goods
Food is too brown and sweet. Texture is crunchy, crisp and brittle.	too much sugar	baked goods
The product lacks flavour and volume.	too little sugar	baked goods and desserts
The product tastes 'eggy' or has a dense texture.	too much egg	baked goods
The product has not set/has little coagulation.	too little egg	cakes, custard, quiche
The consistency is too runny for a batter or sauce.	too much liquid	baked goods and sauces
The mixture is very dry.	too little liquid	baked goods and sauces
The cake surface is cracked, or the cake has risen over the tin.	too much raising agent	bread, biscuits, cake
The product hasn't risen at all and is very dense.	too little raising agent	bread, biscuits, cake

What Do Ingredients Do?

Ingredient	Purpose
Flour	 provides bulk and volume; thickens liquids (gelatinisation).
Fat	adds flavour, colour and moisture; traps air.
Sugar	adds flavour, colour and texture.
Eggs	adds flavour, colour and air;helps set the liquid (coagulation).
Baking powder	produces carbon dioxide bubbles, resulting in cakes being able to rise.
Yeast	 produces carbon dioxide bubbles, resulting in bread dough being able to rise.
